Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

	temperature of the solid is becoming equal to the temperature of drying air. BC is straight line that to x-axis in presenting constant rate of drying during which the layers of water on the surface of solid is being evaporated. The section CE of the curve represents the falling rate period composing of first falling rate period CD and second falling rate period DE from point C onwards some dry patches have started forming on the surface of the solid. The rate of drying decreases for the unsaturated portion and hence rate for total surface portion and hence rate for total surface decreases. The section CD of the curve represents the period corresponding to the zone of unsaturated surface drying the moisture content at which constant rate period ends is known as critical moisture content. After point D, the surface of the solid is completely dry and now internal movement of moistures starts coming to the surface and this is continued up to the point E, where eqm. Is attained the rate of drying over section DE is governed by the internal moisture movement.

Page **6 of 25**

	<p>relationship is represented by the super solubility curve which is approximately parallel tp the solubility curve. The curve AB is the solubility curve and curve PQ is the super solubility curve. The curve AB represents maximum conc of solution which can be achieved by bringing solid-solute into eqm with liquid solvent. If a solution having the composition and temp indicated by point C is cooled in the direction shown by the arrow it first crosses the solubility curve AB and it is expected to start of crystallization. Actually if the process started with initially unseeded solution crystal formation will not begin until the solution is super cooled considerably passed the curve AB. According to Mier's theory , crystallization will start in the neighbourhood of the point D and the concentration of the solution then follows roughly along the curve DE. For an initially unseeded solution , the curve PQ represents the limit at which spontaneous nuclei formation begin and consequently, crystallization can start.</p>  <p>2</p>

2

In liquid liquid extraction when the solvent is partially miscible with the original solvent , the solubility and equilibrium relations are often shown on a triangular diagram. The composition of ternary system can be shown by a point lying inside an equilateral triangle. Consider a system C (acetone).A (water),B (methyl isobutyl ketone) at 250C wherein acetone is solute , water is diluents and MIK is solvent for extracting the solute. Apex C in the triangle ABC represent 100% acetone and apex Aand B represent 100% water and 100% MIK respectively.Along line BC,concentration of Ais zero and the same is true for B and C along AC and AB.

2

The ternary system represented by point P consist of three components C,A,B in the ratio of perpendiculars PL,PJ and PK respectively.The distances AD and BE represent the solubility of solvent B in A and A in B. The curve the line ERF indicates composition of saturated MIK layer and the curve line DQF represent the composition of saturated water layer. The area under binodal solubility curve represented by the curve line DQFRE represent a two phase region that will splitup into two layers in equilibrium with each other.The point F on the curve represents a single phase which does not split into two phases and corresponds to tie line of zero length and is known as plate point.

Page 11 of 25

Similarly, evaluate α at other temperatures.

$$\text{At } 366.3 \text{ K, } \alpha = 5.32$$

$$\text{At } 380.2 \text{ K, } \alpha = 4.91$$

$$\text{At } 394.1 \text{ K, } \alpha = 4.59$$

$$\text{At } 398.6 \text{ K, } \alpha = 4.50$$

$$\text{Average value of } \alpha = \frac{6.29 + 5.91 + 5.32 + 4.91 + 4.59 + 4.50}{6} = 5.25$$

We know that,

$$y = \frac{\alpha x}{1 + (\alpha - 1) x}$$

Where x and y are the mole fraction of hexane in the liquid and the vapour phases, respectively.

$$y = \frac{5.25 x}{1 + (5.25 - 1) x}$$

$$y = \frac{5.25 x}{1 + 4.25 x}$$

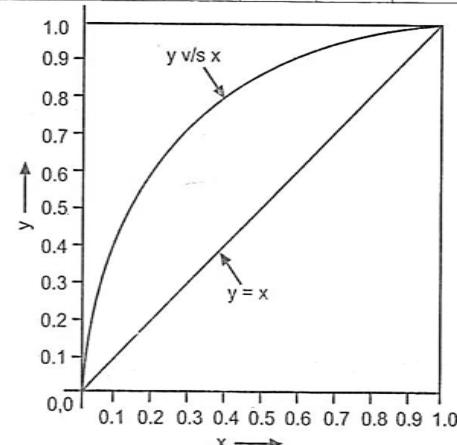

... Ans.

Above is the desired empirical relation between y and x . Take $x = 0, 0.10, 0.20 \dots 1.0$ and evaluate corresponding values of y from above relation.

e.g., Take $x = 0.20$

$$y = \frac{5.25 \times (0.20)}{1 + 4.25 (0.20)} = 0.57$$

x	0.0	0.10	0.20	0.30	0.40	0.50	0.60	0.70	0.80	0.90	1.0

$$N_A = J_A + \alpha n (N_A + N_B) \\ = -D_{AB} \frac{dc_A}{dz} + c_A (N_A + N_B)$$

For ideal gas $P_A = C_A RT$

$$c_A = \frac{P_A}{RT}$$

$$dc_A = \frac{dP_A}{RT}$$

$$c = \frac{P}{RT}$$

1

Putting values of c_A , dc_A & c

$$N_A = -D_{AB} \frac{dP_A}{RT} \frac{1}{dz} + \frac{P_A/RT}{P/RT} (N_A + N_B)$$

For equimolar counter diffusion, $N_A = -N_B$

$$\therefore N_A = -\frac{D_{AB}}{RT} \frac{dP_A}{dz}$$

1

If D_{AB} is constant, flux can be integrated

$$N_A \int_{z_1}^{z_2} dz = -\frac{D_{AB}}{RT} \int_{P_{A1}}^{P_{A2}} dP_A$$

$$N_A (z_2 - z_1) = -\frac{D_{AB}}{RT} (P_{A2} - P_{A1})$$

$$N_A z = +\frac{D_{AB}}{RT} (P_{A1} - P_{A2})$$

1

$$N_A = \frac{D_{AB}}{RT z} (P_{A1} - P_{A2})$$

	<p>Draw the equilibrium curve and draw the operating line with the slope to -1 passing through (0.6,0.6) on the diagonal. It intersects the equilibrium curve at P which gives us the equilibrium liquid and vapour compositions as 0.41 and 0.79 mole fraction hexane respectively.</p>	1
5-e	<p>Rotating disk contactor: Rotating disk contactor is a mechanically agitated counter current extractor wherein agitation is brought with the help of rotating disk which usually runs at much higher speed than turbine type impeller.</p>  <p>Rotating disc contactor for light phase dispersed It consists of a cylindrical column that is divided into a number of compartments formed by a series of stator rings. Each compartment contains centrally located horizontal rotor disk that create high degree of turbulence inside the column. The diameter of the rotor disk is less than the opening in the stationery stator rings, usually the disk diameter is 33 to 66 % of the column diameter. Recommended compartment height for column of diameter 2 m is</p>	2

	200 to 300 mm. The tower is provided with inlet & outlet connections at top & bottom from light and heavy phases. Fig. represents rotating-disk contactor for light phase dispersed. In these units, disk disperse the liquids and impel them outward towards tower wall, where stator rings create quiet zones where in the two phases can separate. It has reasonable capacity, low operating cost and high efficiency. While dealing with corrosive liquids it is very difficult to maintain the internal moving parts.

6-a	Solubility of $\text{Na}_2\text{S}_2\text{O}_3$ is 70 parts per 100 parts water at $293\text{ K}(20^\circ\text{C})$ Basis: 100 kg of feed solution. It contains 48 kg $\text{Na}_2\text{S}_2\text{O}_3$ and 52 kg of water. Let 'C' be the yield of crystals. $M_1 = \text{Molecular weight of } \text{Na}_2\text{S}_2\text{O}_3 = 158$ $M_2 = \text{Molecular weight of } \text{Na}_2\text{S}_2\text{O}_3, 5\text{H}_2\text{O} = 248$ $X_F = 48/100 = 0.48$ Material balance of water : Water in feed = Water of crystallization in crystals + Water in mother liquor. $52 = C \cdot ((M_2 - M_1)/M_2) + L'$ $L' = 52 - C[248 - 158]/248$ Material balance of solute: Solute in feed = Solute in crystals produced + Solute in mother liquor $0.48 \times 100 = c(158/248) + [52 - ((248 - 158)/248)C]X'$ $48 = 0.637C + [52 - 0.363C]x(70/100)$ C=30.3 kg. Crystals in feed solution = $48 \times (248/158) = 73.34\text{ kg}$ % yield of hydrated crystals = $(30.3/73.34) = 41.31$	1 1 1 1 1 1 1 1 1 1 1

6-c	<p>Drum dryer</p> <p>The diagram illustrates a drum dryer system. At the top, there is a vapor hood with a 'Moisture out' pipe. Below it is an 'Internally steam heated drum'. A curved arrow indicates the rotation of the drum. At the bottom, there is a trough containing material. An 'Agitator' is located in the center of the trough, with a 'Spreader' positioned above it. A 'Knife' is shown at the edge of the trough. Arrows indicate the flow of material from the agitator into the trough and the exit of dried material from the bottom right. The entire unit is labeled 'Drum dryer'.</p> <p>Working :</p>	4

	A slowly revolving internally steam heated drum continuously dips into a drum and picks up the feed which retains on the drum surface as a thin film. The thickness of this film of material is regulated by means of a spreader. During the course of revolution of the drum the material is dried due to heat transfer from condensing steam through the metal wall of the drum and large surface area. As it reaches the other end the dried product of operation is scraped by knife. The moisture evaporated from the feed material is collected and removed through a vapour hood provided above the drum.	4
